| Background :                       | Histones are basic nuclear proteins that are responsible for the nucleosome structure of the chromosomal fiber in eukaryotes. This structure consists of approximately 146 bp of DNA wrapped around a nucleosome, an octamer composed of pairs of each of the four core histones (H2A, H2B, H3, and H4). The chromatin fiber is further compacted through the interaction of a linker histone, H1, with the DNA between the nucleosomes to form higher order chromatin structures. This gene is intronless and encodes a replication-dependent histone that is a member of the histone H3 family. Transcripts from this gene lack polyA tails; instead, they contain a palindromic termination element. This gene is found in the large histone gene cluster on chromosome 6p22-p21.3. [provided by RefSeq, Aug 2015],                                                                                                                                                   |
| Function :                         | caution:Was originally (PubMed:2587222) thought to originate from<br>mouse.,developmental stage:Expressed during S phase, then expression strongly<br>decreases as cell division slows down during the process of<br>differentiation.,function:Core component of nucleosome. Nucleosomes wrap and<br>compact DNA into chromatin, limiting DNA accessibility to the cellular<br>machineries which require DNA as a template. Histones thereby play a central<br>role in transcription regulation, DNA repair, DNA replication and chromosomal<br>stability. DNA accessibility is regulated via a complex set of post-translational<br>modifications of histones, also called histone code, and nucleosome<br>remodeling.,mass spectrometry:Monoisotopic with N-acetylserine<br>PubMed:16457589,miscellaneous:This histone is only present in mammals and is<br>enriched in acetylation of Lys-15 and dimethylation of Lys-10<br>(H3K9me2).,PTM:Acetylation is generally I |
